## Collaborative Filtering (CF)

## The problem

- Given a set of $n_{\mathcal{X}}$ "movies" $\mathbf{x} \in \mathcal{X}$ and a set of $n_{\mathcal{Y}}$ "customers" $\mathbf{y} \in \mathcal{Y}$,
- predict the "rating" $z(\mathbf{x}, \mathbf{y}) \in \mathcal{Z}$ of customer $\mathbf{y}$ for movie $\mathbf{x}$
- Training data: large $n_{\mathcal{X}} \times n_{\mathcal{Y}}$ incomplete matrix $Z$ that describes the known ratings of some customers for some movies
- Goal: complete the matrix.

|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

## Another CF example

## Drug design

- Given a family of proteins of therapeutic interest (e.g., GPCR's)
- Given all known small molecules that bind to these proteins
- Can we predict unknown interactions?

## CF by low-rank matrix approximation

- A common strategy for CF
- $Z$ has rank less than $k \Leftrightarrow Z=U V^{\top} U \in \mathbb{R}^{n_{\mathcal{X}} \times k}, V \in \mathbb{R}^{n_{\mathcal{Y}} \times k}$
- Examples: PLSA (Hoffmann, 2001), MMMF (Srebro et al, 2004)
- Numerical and statistical efficiency

## CF by low-rank matrix approximation example

## Fitting low-rank models (Srebro et al, 2004)

- Relax the (non-convex) rank of $Z$ into the (convex) trace norm of $Z$ : if $\sigma_{i}(Z)$ are the singular values of $Z$,

$$
\operatorname{rank} Z=\sum_{i} 1_{\sigma_{i}(Z)>0} \quad\|Z\|_{*}=\sum_{i} \sigma_{i}(Z)
$$

- $n$ observations $z_{u}$ corresponding to $\mathbf{x}_{i(u)}$ and $\mathbf{y}_{j(u)}, u=1$
where $\ell\left(z, z^{\prime}\right)$ is a convex loss function.
- This is an SDP if $\ell$ is SDP-representable

## CF by low-rank matrix approximation example

## Fitting low-rank models (Srebro et al, 2004)

- Relax the (non-convex) rank of $Z$ into the (convex) trace norm of $Z$ : if $\sigma_{i}(Z)$ are the singular values of $Z$,

$$
\operatorname{rank} Z=\sum_{i} 1_{\sigma_{i}(Z)>0} \quad\|Z\|_{*}=\sum_{i} \sigma_{i}(Z)
$$

- $n$ observations $z_{u}$ corresponding to $\mathbf{x}_{i(u)}$ and $\mathbf{y}_{j(u)}, u=1, \ldots, n$ :

$$
\min _{z \in \mathbb{R}^{n} \mathcal{X} \times n y} \sum_{u=1}^{n} \ell\left(z_{u}, Z_{i(u), j(u)}\right)+\lambda\|Z\|_{*},
$$

where $\ell\left(z, z^{\prime}\right)$ is a convex loss function.

- This is an SDP if $\ell$ is SDP-representable

## CF with attributes

## The problem

- Often we have additional attributes:
- gender, age of customers; type, actors of movies..
- 3D structures of proteins and ligands for protein-ligand interaction prediction
- How to include attributes in CF?
- Expected gains: increase performance, allow predictions on new movie and/or customers.

## Our contributions

- A general framework for CF with or without attributes, using
kernels to describe attributes ("kernel-CF")
- A family of algorithms for CF in this setting

## CF with attributes

## The problem

- Often we have additional attributes:
- gender, age of customers; type, actors of movies..
- 3D structures of proteins and ligands for protein-ligand interaction prediction
- How to include attributes in CF?
- Expected gains: increase performance, allow predictions on new movie and/or customers.

## Our contributions

- A general framework for CF with or without attributes, using kernels to describe attributes ("kernel-CF")
- A family of algorithms for CF in this setting

## The idea

## Basic facts

- $n_{\mathcal{X}}$ movies and $n_{\mathcal{Y}}$ customers
- The known rating $z\left(\mathbf{x}_{i}, \mathbf{y}_{j}\right)$ of customer $\mathbf{y}_{j}$ for movie $\mathbf{x}_{i}$ is stored in the $(i, j)$-th entry of a matrix $M$ (of size $n_{\mathcal{X}} \times n_{\mathcal{Y}}$ ).
- $M$ represents a linear application / bilinear form:

$$
M: \mathbb{R}^{n_{\mathcal{Y}}} \rightarrow \mathbb{R}^{n_{\mathcal{X}}}
$$

defined by:

$$
e_{i}^{\top} M f_{j}=M_{i, j}
$$

- Rank / trace norm are spectral properties of the linear application

## The idea

## Reformulations

- Represent the $i$-th movie $\mathbf{x}_{i} \in \mathcal{X}$ (resp. $j$-th customer $\mathbf{y}_{j} \in \mathcal{Y}$ ) by the $i$-th basis vector $e_{i} \in \mathbb{R}^{n_{\mathcal{X}}}$ (resp. $f_{j} \in \mathbb{R}^{n_{\mathcal{Y}}}$ ):

$$
\phi_{X}\left(x_{i}\right)=e_{i}, \quad \phi_{Y}\left(y_{j}\right)=f_{j} .
$$

- Approximate the rating function by a bilinear form:

$$
\forall\left(\mathbf{x}_{i}, \mathbf{y}_{j}\right) \in \mathcal{X} \times \mathcal{Y}, \quad G_{M}\left(\mathbf{x}_{i}, \mathbf{y}_{j}\right)=\phi_{X}\left(\mathbf{x}_{i}\right)^{\top} M \phi_{Y}\left(\mathbf{y}_{j}\right),
$$

by constraining a spectral property of $M: \mathbb{R}^{n_{\mathcal{X}}} \mapsto \mathbb{R}^{n_{\mathcal{X}}}$.

## An idea

If we have additional attributes about movies / customer, why not include them in $\phi_{X}(\mathbf{x})$ and $\phi_{Y}(\mathbf{y})$ ?

## The idea

## Reformulations

- Represent the $i$-th movie $\mathbf{x}_{i} \in \mathcal{X}$ (resp. $j$-th customer $\mathbf{y}_{j} \in \mathcal{Y}$ ) by the $i$-th basis vector $e_{i} \in \mathbb{R}^{n_{\mathcal{X}}}$ (resp. $f_{j} \in \mathbb{R}^{n_{\mathcal{Y}}}$ ):

$$
\phi_{X}\left(x_{i}\right)=e_{i}, \quad \phi_{Y}\left(y_{j}\right)=f_{j}
$$

- Approximate the rating function by a bilinear form:

$$
\forall\left(\mathbf{x}_{i}, \mathbf{y}_{j}\right) \in \mathcal{X} \times \mathcal{Y}, \quad G_{M}\left(\mathbf{x}_{i}, \mathbf{y}_{j}\right)=\phi_{X}\left(\mathbf{x}_{i}\right)^{\top} M \phi_{Y}\left(\mathbf{y}_{j}\right)
$$

by constraining a spectral property of $M: \mathbb{R}^{n_{\mathcal{X}}} \mapsto \mathbb{R}^{n_{\mathcal{X}}}$.

## An idea

If we have additional attributes about movies / customer, why not include them in $\phi_{X}(\mathbf{x})$ and $\phi_{Y}(\mathbf{y})$ ?

## Setting

- Movies: points in a Hilbert space $\mathcal{X}$
- Customers: points in a Hilbert space $\mathcal{Y}$
- We model the preference of customer $\mathbf{y}$ for a movie $\mathbf{x}$ by a bilinear form:

$$
f(\mathbf{x}, \mathbf{y})=\langle\mathbf{x}, F \mathbf{y}\rangle_{\mathcal{X}},
$$

where $F \in \mathcal{B}_{0}(\mathcal{Y}, \mathcal{X})$ is a compact linear operator (i.e., a "matrix").

## Spectra of compact operators

## Classical results

- For $(\mathbf{x}, \mathbf{y})$ in $\mathcal{X} \times \mathcal{Y}$ the tensor product $\mathbf{x} \otimes \mathbf{y}$ is the operator

$$
\forall \mathbf{h} \in \mathcal{Y}, \quad(\mathbf{x} \otimes \mathbf{y}) \mathbf{h}=\langle\mathbf{y}, \mathbf{h}\rangle_{\mathcal{Y}} \mathbf{x}
$$

- Any compact operator $F: \mathcal{Y} \rightarrow \mathcal{X}$ admits a spectral decomposition:
where the $\sigma_{i} \geq 0$ are the singular values and $\left(\mathbf{u}_{i}\right)_{i \in \mathbb{N}}$ and $\left(\mathbf{v}_{i}\right)_{i \in \mathbb{N}}$ are orthonormal families in $\mathcal{X}$ and $\mathcal{Y}$.
- The spectrum of $F$ is the set of singular values sorted in decreasing order: $\sigma_{1}(F) \geq \sigma_{2}(F) \geq \ldots \geq 0$.
- This is the natural generalization of singular values for matrices.

## Spectra of compact operators

## Classical results

- For $(\mathbf{x}, \mathbf{y})$ in $\mathcal{X} \times \mathcal{Y}$ the tensor product $\mathbf{x} \otimes \mathbf{y}$ is the operator

$$
\forall \mathbf{h} \in \mathcal{Y}, \quad(\mathbf{x} \otimes \mathbf{y}) \mathbf{h}=\langle\mathbf{y}, \mathbf{h}\rangle_{y} \mathbf{x}
$$

- Any compact operator $F: \mathcal{Y} \rightarrow \mathcal{X}$ admits a spectral decomposition:

$$
F=\sum_{i=1}^{\infty} \sigma_{i} \mathbf{u}_{i} \otimes \mathbf{v}_{i}
$$

where the $\sigma_{i} \geq 0$ are the singular values and $\left(\mathbf{u}_{i}\right)_{i \in \mathbb{N}}$ and $\left(\mathbf{v}_{i}\right)_{i \in \mathbb{N}}$ are orthonormal families in $\mathcal{X}$ and $\mathcal{Y}$.

- The spectrum of $F$ is the set of singular values sorted in decreasing order: $\sigma_{1}(F) \geq \sigma_{2}(F) \geq \ldots \geq 0$.
- This is the natural generalization of sinqular va ues for matrices.

## Spectra of compact operators

## Classical results

- For $(\mathbf{x}, \mathbf{y})$ in $\mathcal{X} \times \mathcal{Y}$ the tensor product $\mathbf{x} \otimes \mathbf{y}$ is the operator

$$
\forall \mathbf{h} \in \mathcal{Y}, \quad(\mathbf{x} \otimes \mathbf{y}) \mathbf{h}=\langle\mathbf{y}, \mathbf{h}\rangle_{\mathcal{Y}} \mathbf{x}
$$

- Any compact operator $F: \mathcal{Y} \rightarrow \mathcal{X}$ admits a spectral decomposition:

$$
F=\sum_{i=1}^{\infty} \sigma_{i} \mathbf{u}_{i} \otimes \mathbf{v}_{i}
$$

where the $\sigma_{i} \geq 0$ are the singular values and $\left(\mathbf{u}_{i}\right)_{i \in \mathbb{N}}$ and $\left(\mathbf{v}_{i}\right)_{i \in \mathbb{N}}$ are orthonormal families in $\mathcal{X}$ and $\mathcal{Y}$.

- The spectrum of $F$ is the set of singular values sorted in decreasing order: $\sigma_{1}(F) \geq \sigma_{2}(F) \geq \ldots \geq 0$.
- This is the natural generalization of singular values for matrices.

## Useful classes for operators

## Operators of finite rank

- The rank of an operator is the number of strictly positive singular values.
- Hence operators of rank smaller or equal to $k$ are characterized by:

$$
\sigma_{k+1}(F)=0
$$

## Trace-class operators <br> The trace-class operators are the compact operators $F$ that satisfy <br> $\square$ is a norm over the trace-class operators, called the trace norm.

## Useful classes for operators

## Operators of finite rank

- The rank of an operator is the number of strictly positive singular values.
- Hence operators of rank smaller or equal to $k$ are characterized by:

$$
\sigma_{k+1}(F)=0
$$

## Trace-class operators

The trace-class operators are the compact operators $F$ that satisfy:

$$
\|F\|_{*}:=\sum_{i=1}^{\infty} \sigma_{i}(F)<\infty
$$

$\|F\|_{*}$ is a norm over the trace-class operators, called the trace norm.

## Useful classes for operators (cont.)

## Hilbert-Schmidt operators

- The Hilbert-Schmidt operators are compact operators $F$ that satisfy:

$$
\|F\|_{\text {Fro }}^{2}:=\sum_{i=1}^{\infty} \sigma_{i}(F)^{2}<\infty .
$$

- They form a Hilbert space with inner product:

$$
\left\langle\mathbf{x} \otimes \mathbf{y}, \mathbf{x}^{\prime} \otimes \mathbf{y}^{\prime}\right\rangle_{\mathcal{X} \otimes \mathcal{Y}}=\left\langle\mathbf{x}, \mathbf{x}^{\prime}\right\rangle_{\mathcal{X}}\left\langle\mathbf{y}, \mathbf{y}^{\prime}\right\rangle_{\mathcal{Y}} .
$$

## Spectral penalty function

## Definition

A function $\Omega: \mathcal{B}_{0}(\mathcal{Y}, \mathcal{X}) \mapsto \mathbb{R} \cup\{+\infty\}$ is called a spectral penalty function if it can be written as:

$$
\Omega(F)=\sum_{i=1}^{\infty} s_{i}\left(\sigma_{i}(F)\right)
$$

where for any $i \geq 1, s_{i}: \mathbb{R}^{+} \mapsto \mathbb{R}^{+} \cup\{+\infty\}$ is a non-decreasing penalty function satisfying $s_{i}(0)=0$.

## Spectral penalty function

## Examples

- Rank constraint: take $s_{k+1}(0)=0$ and $s_{k+1}(u)=+\infty$ for $u>0$, and $s_{i}=0$ for $i \geq k$. Then

$$
\Omega(F)= \begin{cases}0 & \text { if } \operatorname{rank}(F) \leq k \\ +\infty & \text { if } \operatorname{rank}(F)>k\end{cases}
$$

- Trace norm: take $s_{i}(u)=u$ for all $i$, then:
- Hilbert-Schmidt norm: take $s_{i}(u)=u^{2}$ for all $i$, then

## Spectral penalty function

## Examples

- Rank constraint: take $s_{k+1}(0)=0$ and $s_{k+1}(u)=+\infty$ for $u>0$, and $s_{i}=0$ for $i \geq k$. Then

$$
\Omega(F)= \begin{cases}0 & \text { if } \operatorname{rank}(F) \leq k \\ +\infty & \text { if } \operatorname{rank}(F)>k\end{cases}
$$

- Trace norm: take $s_{i}(u)=u$ for all $i$, then:

$$
\Omega(F)=\|F\|_{*} .
$$

- Hilbert-Schmidt norm: take $s_{i}(u)=u^{2}$ for all $i$, then

## Spectral penalty function

## Examples

- Rank constraint: take $s_{k+1}(0)=0$ and $s_{k+1}(u)=+\infty$ for $u>0$, and $s_{i}=0$ for $i \geq k$. Then

$$
\Omega(F)= \begin{cases}0 & \text { if } \operatorname{rank}(F) \leq k \\ +\infty & \text { if } \operatorname{rank}(F)>k\end{cases}
$$

- Trace norm: take $s_{i}(u)=u$ for all $i$, then:

$$
\Omega(F)=\|F\|_{*}
$$

- Hilbert-Schmidt norm: take $s_{i}(u)=u^{2}$ for all $i$, then

$$
\Omega(F)=\|F\|_{\text {Fro }}^{2} .
$$

## Learning operator with spectral regularization

## Setting

- Training set: $\left(\mathbf{x}_{i}, \mathbf{y}_{i}, t_{i}\right)_{i=1, \ldots, N}$ a set of (movie,customer,preference).
- Loss function $I\left(t, t^{\prime}\right)$ : cost of predicting preference $t$ instead of $t^{\prime}$.
- Empirical risk of an operator $F$ :

$$
R_{N}(F)=\frac{1}{N} \sum_{i=1}^{N} I\left(\left\langle\mathbf{x}_{i}, F \mathbf{y}_{i}\right\rangle_{\mathcal{X}}, t_{i}\right) .
$$

## Learning an operator

## Learning operator with spectral regularization

## Setting

- Training set: $\left(\mathbf{x}_{i}, \mathbf{y}_{i}, t_{i}\right)_{i=1, \ldots, N}$ a set of (movie,customer,preference).
- Loss function $I\left(t, t^{\prime}\right)$ : cost of predicting preference $t$ instead of $t^{\prime}$.
- Empirical risk of an operator $F$ :

$$
R_{N}(F)=\frac{1}{N} \sum_{i=1}^{N} I\left(\left\langle\mathbf{x}_{i}, F \mathbf{y}_{i}\right\rangle_{\mathcal{X}}, t_{i}\right) .
$$

## Learning an operator

$$
\min _{F \in \mathcal{B}_{0}(\mathcal{Y}, \mathcal{X}), \Omega(F)<\infty}\left\{R_{N}(F)+\lambda \Omega(F)\right\} .
$$

## Questions

## Theory

Is it a "good" algorithm in theory?

- To be investigated...
- See Srebro et al. (2004), Bach (2007) for preliminary results with the trace norm

## Practice

Can we implement it? Does it work on real data?

- Optimization problem in the space of compact operators... but we show later that it boils down to a finite-dimensional optimization problem
- Promising results on real data

## A classical representer theorem

## Theorem

If $\hat{F}$ is a solution the problem:

$$
\min _{F \in \mathcal{B}_{2}(\mathcal{Y}, \mathcal{X})}\left\{R_{N}(F)+\lambda \sum_{i=1}^{\infty} \sigma_{i}(F)^{2}\right\},
$$

then it is necessarily in the linear span of $\left\{\mathbf{x}_{i} \otimes \mathbf{y}_{i}: i=1, \ldots, N\right\}$, i.e., it can be written as:

$$
\hat{F}=\sum_{i=1}^{N} \alpha_{i} \mathbf{x}_{i} \otimes \mathbf{y}_{i},
$$

for some $\alpha \in \mathbb{R}^{N}$.

## Proof sketch

- $\mathcal{B}_{2}(\mathcal{Y}, \mathcal{X})$ is isomorphic to the RKHS of the tensor product kernel:

$$
k_{\otimes}\left((\mathbf{x}, \mathbf{y}),\left(\mathbf{x}^{\prime}, \mathbf{y}^{\prime}\right)\right)=\left\langle\mathbf{x}, \mathbf{x}^{\prime}\right\rangle_{\mathcal{X}}\left\langle\mathbf{y}, \mathbf{y}^{\prime}\right\rangle_{\mathcal{Y}},
$$

by $f(\mathbf{x}, \mathbf{y})=\langle\mathbf{x}, F \mathbf{y}\rangle_{\mathcal{X}}$. In particular,

$$
\|f\|_{\mathcal{H}_{\otimes}}^{2}=\|F\|^{2}=\Omega(F) .
$$

- The problem is therefore a classical kernel method:

$$
\min _{f \in \mathcal{H}_{\otimes}}\left\{R_{N}(f)+\lambda\|f\|_{\otimes}^{2}\right\},
$$

so the classical representer theorem can be used.

## A generalized representer theorem

## Theorem

For any spectral penalty function $\Omega: \mathcal{B}_{0}(\mathcal{Y}, \mathcal{X}) \mapsto \mathbb{R}$, let the optimization problem:

$$
\min _{F \in \mathcal{B}_{0}(y, \mathcal{X}), \Omega(F)<\infty}\left\{R_{N}(F)+\lambda \Omega(F)\right\} .
$$

If the set of solutions is not empty, then there is a solution $F$ in $\mathcal{X}_{N} \otimes \mathcal{Y}_{N}$, i.e., there exists $\alpha \in \mathbb{R}^{m_{\mathcal{X}} \times m_{y}}$ such that:

$$
F=\sum_{i=1}^{m_{x}} \sum_{j=1}^{m_{y}} \alpha_{i j} \mathbf{u}_{i} \otimes \mathbf{v}_{j},
$$

where $\left(\mathbf{u}_{1}, \ldots, \mathbf{u}_{m_{\mathcal{X}}}\right)$ and $\left(\mathbf{v}_{1}, \ldots, \mathbf{v}_{m_{y}}\right)$ form orthonormal bases of $\mathcal{X}_{N}$ and $\mathcal{Y}_{N}$, respectively.

## Proof sketch

- For any operator $F \in \mathcal{B}_{0}(\mathcal{Y}, \mathcal{X})$, let

$$
G=\Pi_{\mathcal{X}_{N}} F \Pi_{\mathcal{Y}_{N}}
$$

where $\Pi_{U}$ is the orthogonal projection onto $U$.

- Lemma: we can show that for all $i \geq 0$ :

$$
\sigma_{i}(G) \leq \sigma_{i}(F)
$$

- Therefore $\Omega(G) \leq \Omega(F)$.
- On the other hand $R_{N}(G)=R_{N}(F)$.
- Consequently for any solution $F$ we have another solution $G \in \mathcal{X}_{N} \otimes \mathcal{Y}_{N}$.

## Practical consequence

## Theorem (cont.)

The coefficients $\alpha$ that define the solution by

$$
F=\sum_{i=1}^{m_{\mathcal{X}}} \sum_{j=1}^{m_{\mathcal{Y}}} \alpha_{i j} \mathbf{u}_{i} \otimes \mathbf{v}_{j}
$$

can be found by solving the following finite-dimensional optimization problem:

$$
\min _{\alpha \in \mathbb{R}^{m} \times m_{\mathcal{X}}, \Omega(\alpha)<\infty} R_{N}\left(\operatorname{diag}\left(X \alpha Y^{\top}\right)\right)+\lambda \Omega(\alpha)
$$

where $\Omega(\alpha)$ refers to the spectral penalty function applied to the matrix $\alpha$ seen as an operator from $\mathbb{R}^{m_{\mathcal{Y}}}$ to $\mathbb{R}^{m_{\mathcal{X}}}$, and $X$ and $Y$ denote any matrices that satisfy $K=X X^{\top}$ and $G=Y Y^{\top}$ for the two Gram matrices $K$ and $G$ of $\mathcal{X}_{N}$ and $\mathcal{Y}_{N}$.

## Summary

We obtain various algorithms by choosing:
(1) A loss function (depends on the application)
(2) A spectral regularization (that is amenable to optimization)
(0) Two Gram matrices (aka kernel matrices)

Both kernels and spectral regularization can be used to constrain the solution

## A family of kernels

Taken $K_{\otimes}=K \times G$ with

$$
\left\{\begin{array}{l}
K=\eta K_{\text {Attribute }}^{x}+(1-\eta) K_{\text {Dirac }}^{x}, \\
G=\zeta K_{\text {Attribute }}^{y}+(1-\zeta) K_{\text {Dirac }}^{y},
\end{array}\right.
$$

for $0 \leq \eta \leq 1$ and $0 \leq \zeta \leq 1$

## Simulated data

## Experiment

- Generate data $(\mathbf{x}, \mathbf{y}, z) \in \mathbb{R}^{f_{x}} \times \mathbb{R}^{f_{y}} \times \mathbb{R}$ according to

$$
z=\mathbf{x}^{\top} B \mathbf{y}+\varepsilon
$$

- Observe only $n_{X}<f_{X}$ and $n_{Y}<f_{Y}$ features
- Low-rank assumption will find the missing features
- Observed attributes will help the low-rank formulation to concentrate mostly on the unknown features
- Comparison of
- Low-rank constraint without tracenorm (note that it requires regularization)
- Trace-norm formulation (regularization is implicit)

## Simulated data: results

- Compare MSE
- Left: rank constraint (best: 0.1540), right: trace norm (best: 0.1522)

## Movies

- MovieLens 100k database, ratings with attributes
- Experiments with 943 movies and 1,642 customers, 100,000 rankings in $\{1, \ldots, 5\}$
- Train on a subset of the ratings, test on the rest
- error measured with MSE (best constant prediction: 1.26)

## Conclusion

## What we saw

- A general framework for CF with or without attributes
- A generalized representation theorem valid for any spectral penalty function
- A family of new methods

## Future work

- The bottleneck is often practical optimization. Online version possible.
- Automatic choice of the kernel
